De novo synthesis of a sunscreen compound in vertebrates

Andrew R Osborn, et al.

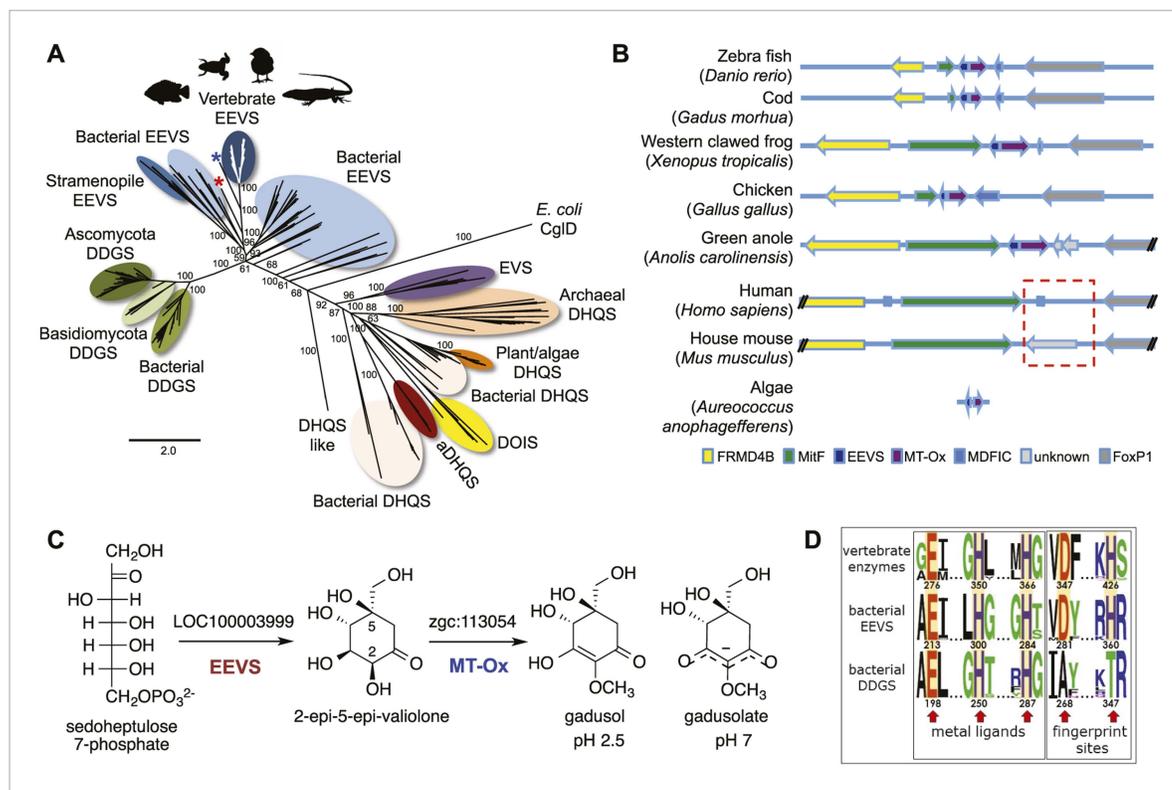

Figure 1. Bioinformatic analysis of sugar phosphate cyclases in prokaryotes and eukaryotes and biochemical characterization of gadusol biosynthetic enzymes. **(A)** Bayesian phylogenetic tree of SPCs. Numbers represent posterior probability. The stramenopile *Aureococcus anophagefferens*, denoted by the blue star, has EEVS and MT-Ox proteins strikingly similar (over 50% identical) to those in vertebrates. The micro algae *Coccomyxa subellipsoidea*, denoted by the red star, also has EEVS and MT-Ox. **(B)** Genetic organizations of EEVS and MT-Ox genes in fish, amphibians, birds, and reptiles. Humans and other mammals lack these genes (indicated in dashed red box). For a complete list of vertebrates whose genomes are known to contain EEVS and MT-Ox genes, see [Table 1](#). FRMD4B, FERM domain-containing protein-4B; MitF, microphthalmia-associated transcription factor; MDFIC, MyoD-family inhibitor domain-containing protein-like; and FoxP1, Forkhead-related transcription factor 1. **(C)** Biochemical characterization of recombinant LOC100003999 and zgc:113054 proteins. **(D)** WebLogo ([Crooks et al., 2004](#)) images of residue conservation patterns at the three metal ligand positions and two active site fingerprint sites known ([Kean et al., 2014](#)) to distinguish bacterial EEVSs from DDGSs. The residue numbers given correspond to the reference proteins *D. rerio* EEVS, ValA, and *A. variabilis* DDGS, respectively. WebLogos were based on 126 vertebrate, 63 bacterial EEVS, and 160 bacterial DDGS sequences, respectively, that had BLASTP E-values $<10^{-120}$ in searches using the reference proteins noted above as queries. Each group was aligned using ProMals ([Pei and Grishin, 2007](#)).

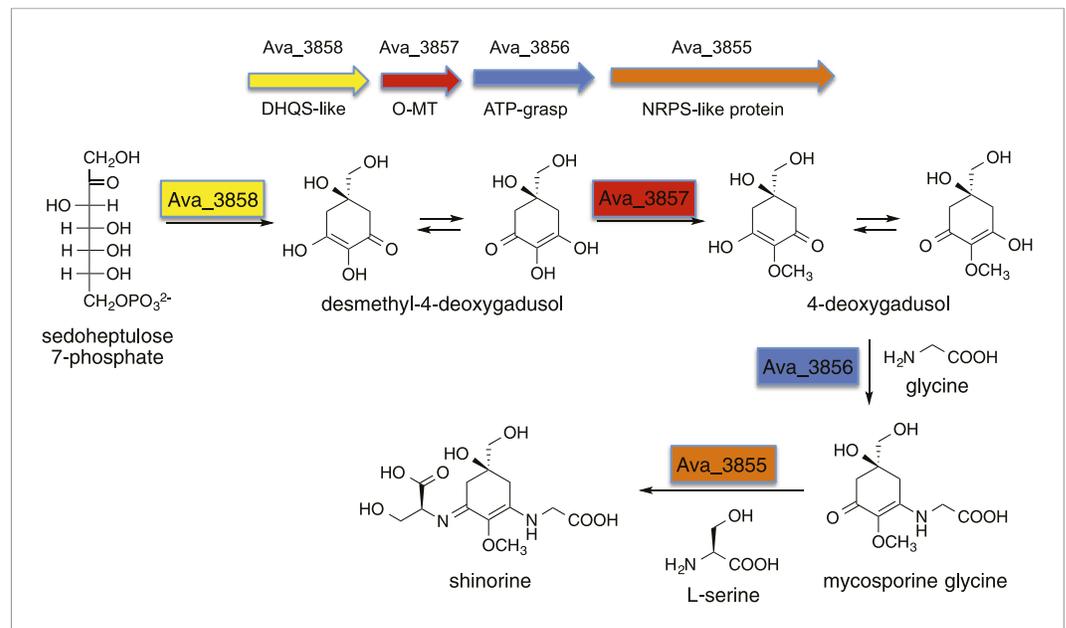

Figure 1—figure supplement 1. Biosynthetic pathway to shinorine in *Anabaena variabilis* (Balskus and Walsh, 2010).

DOI: 10.7554/eLife.05919.005

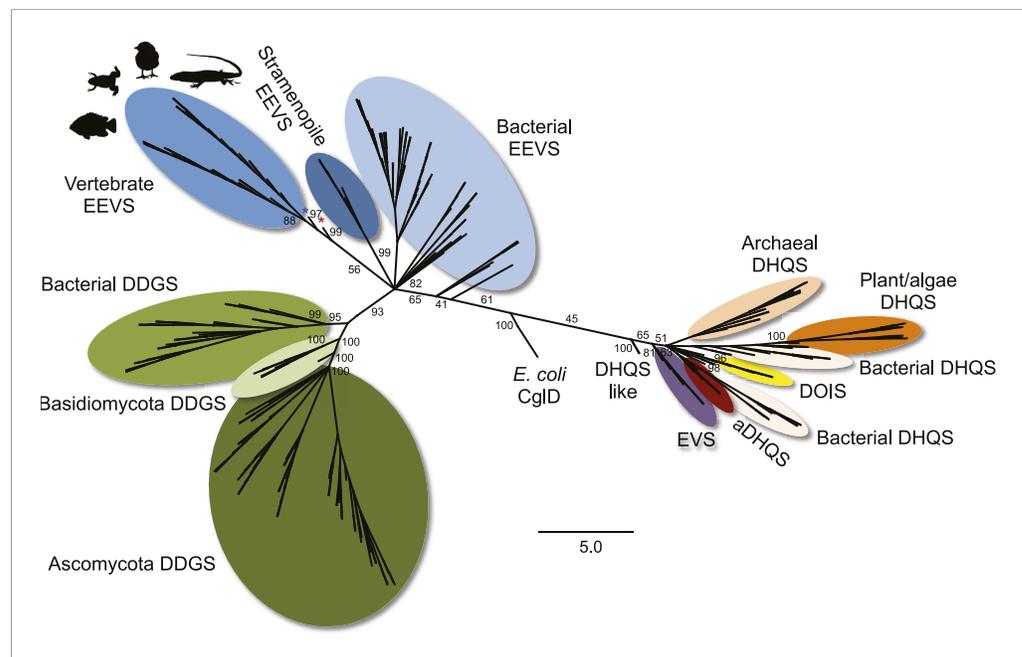

Figure 1—figure supplement 2. Maximum likelihood phylogenetic tree of sugar phosphate cyclases. Numbers represent bootstrap confidence values. Blue star denotes the stramenopile *A. anophagefferens*, and red star denotes the micro algae *C. subellipsoidea*.

DOI: 10.7554/eLife.05919.006

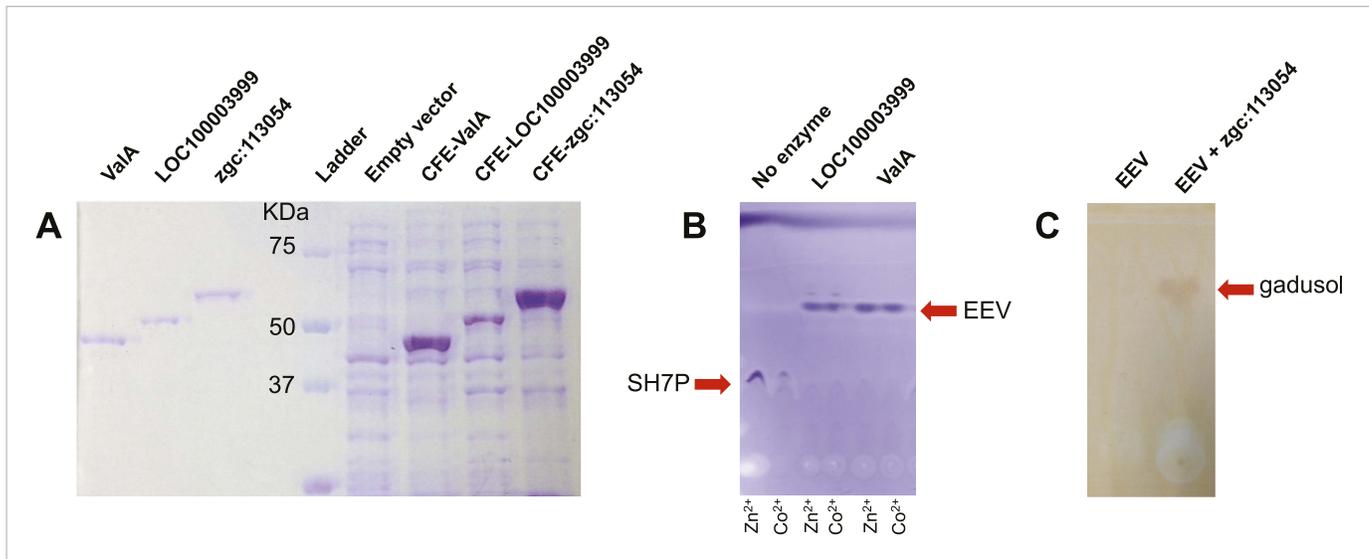

Figure 1—figure supplement 3. SDS PAGE of EEVs and MT-Ox proteins and thin-layer chromatography (TLC) analysis of their products. **(A)** SDS PAGE of purified recombinant ValA, LOC100003999, and zgc:113054, and *E. coli* cell free extracts containing the enzymes. **(B)** TLC analysis of enzymatic products of purified ValA and purified LOC100003999. **(C)** TLC analysis of EEV and the zgc:113054 product (gadusol) using FeCl₃ solution as a spraying agent. Only gadusol, but not EEV, can be detected as a maroon spot.

DOI: [10.7554/eLife.05919.007](https://doi.org/10.7554/eLife.05919.007)

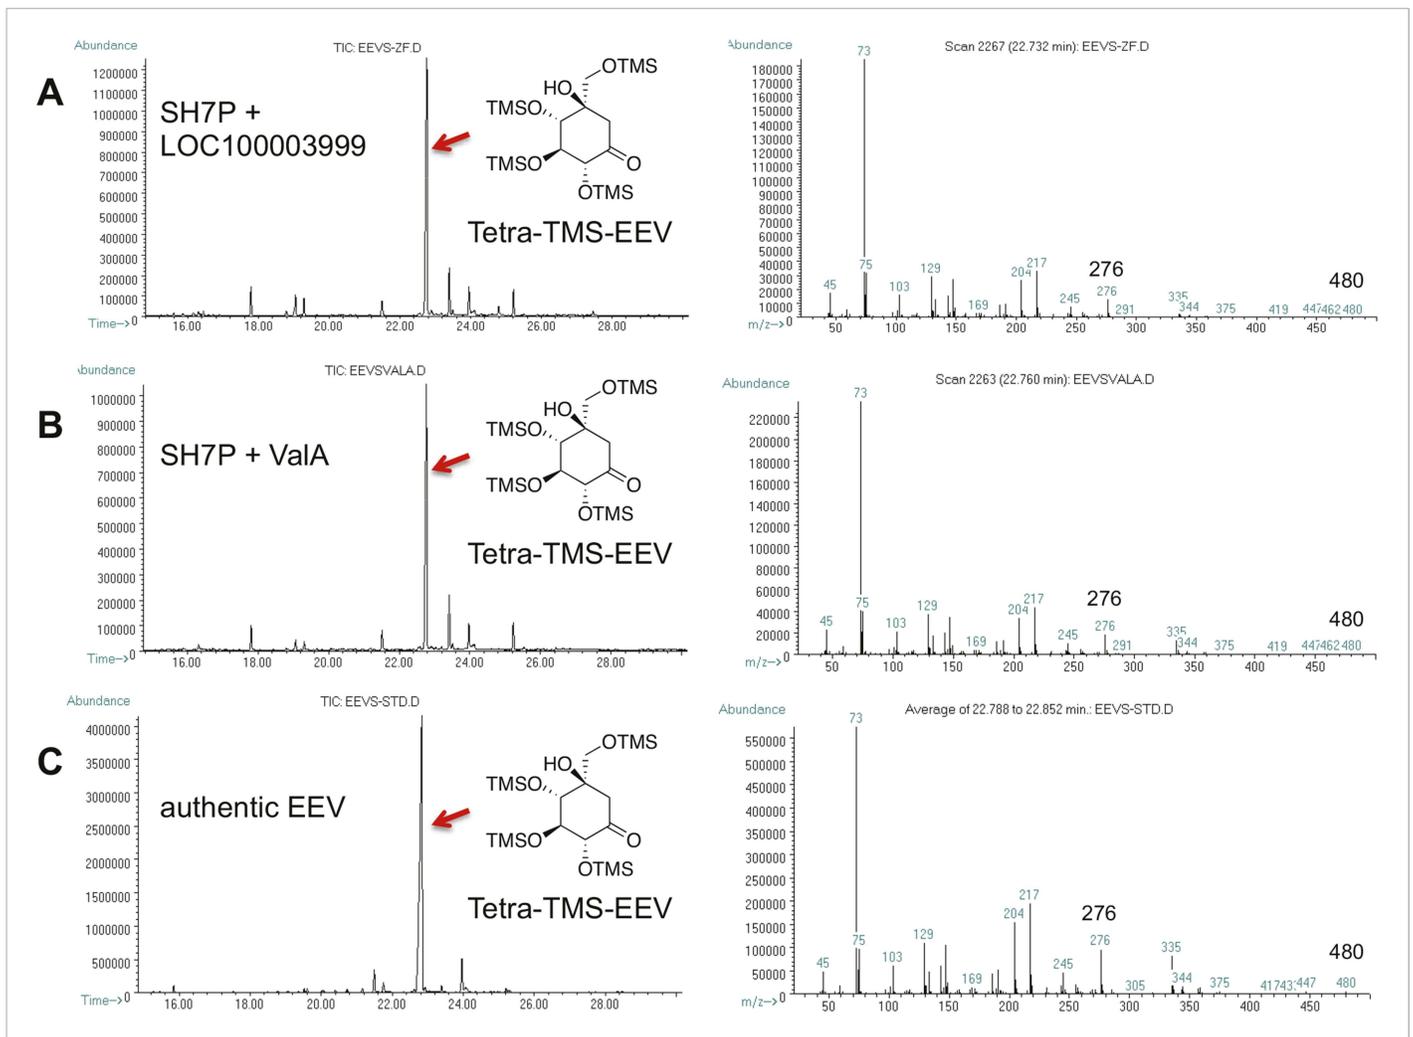

Figure 1—figure supplement 4. GC-MS analysis of LOC100003999 and ValA reaction products. **(A)** SH7P with *E. coli* cell free extracts containing LOC100003999. **(B)** SH7P with purified ValA. **(C)** Authentic EEV. Samples were converted to their trimethylsilyl derivatives using Tri-Sil HTP (Thermo Scientific).

DOI: [10.7554/eLife.05919.008](https://doi.org/10.7554/eLife.05919.008)

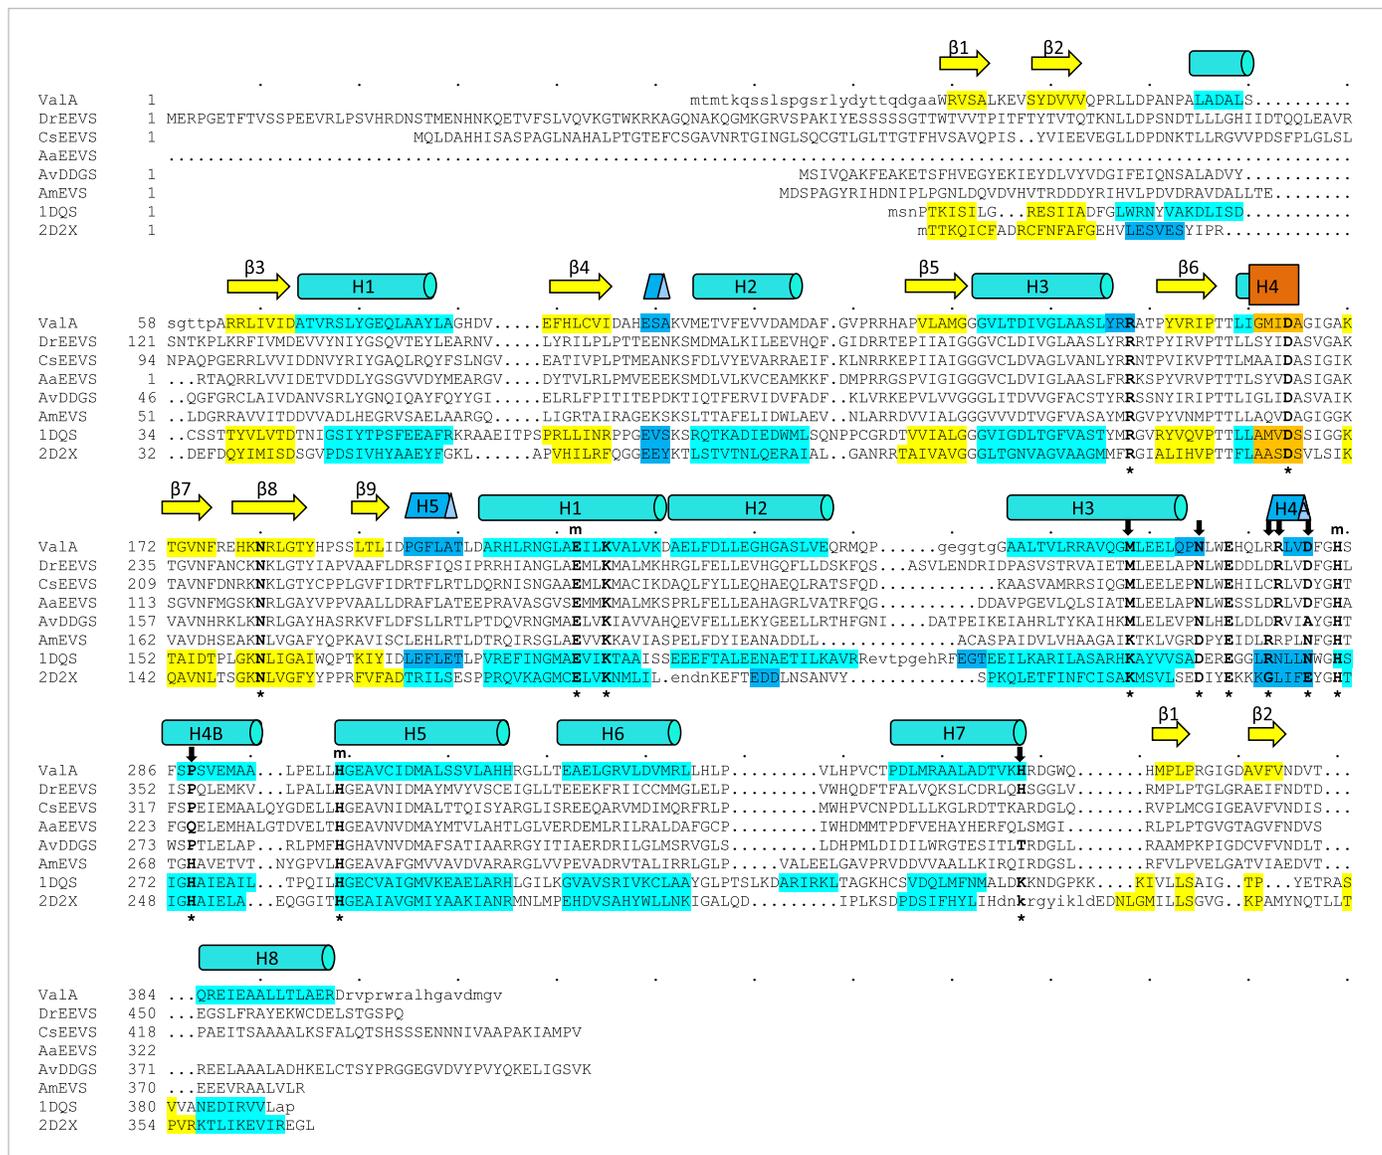

Figure 1—figure supplement 5. Sequences of the vertebrate clade of EEVS-related proteins have characteristic features of an EEVS. Alignment of the sequence of the only structurally known EEVS—ValA from *Streptomyces hygroscopicus* (ShEEVS; PDB entry 4P53) with representative related enzymes. The family consensus secondary structure elements shown schematically above the sequences and within each sequence the residues involved in secondary structures are color coded: β -strands (yellow), α -helices (teal), 3_{10} helices (blue), and π helices (orange). ValA is shown first, and other sequences in order are DrEEVS (*Danio rerio* EEVS), CsEEVS (*C. subellipsoidea* EEVS), AaEEVS (*A. anophagefferens* EEVS), AvDDGS (*A. variabilis* DDGS; Ava_3858), AmEVS (*Actinosynnema mirum* EVS; Amir_2000), PDB entry 1DQS (*Aspergillus nidulans* DHQS), and PDB entry 2D2X (*Bacillus circulans* DOIS). The 14 ‘fingerprint’ active site positions identified by Kean et al. (Kean et al., 2014) are indicated by an asterisk (*) below the sequences. Above the sequences are indicated a subset of those residues that ligate the catalytic metal (m) and another subset with notable variation between the family members that have different types of activity (l). The DrEEVS sequence and those of all known vertebrate homologs (not shown) match ShEEVS at all fourteen active site positions. The putative algal EEVS enzymes, AaEEVS and CsEEVS, sequences match the EEVS residues at the positions thought to be important for distinguishing the EEVS activity, but respectively differ at one and two positions; these positions are the ones that are of unknown importance for EEVS activity.

DOI: 10.7554/eLife.05919.009

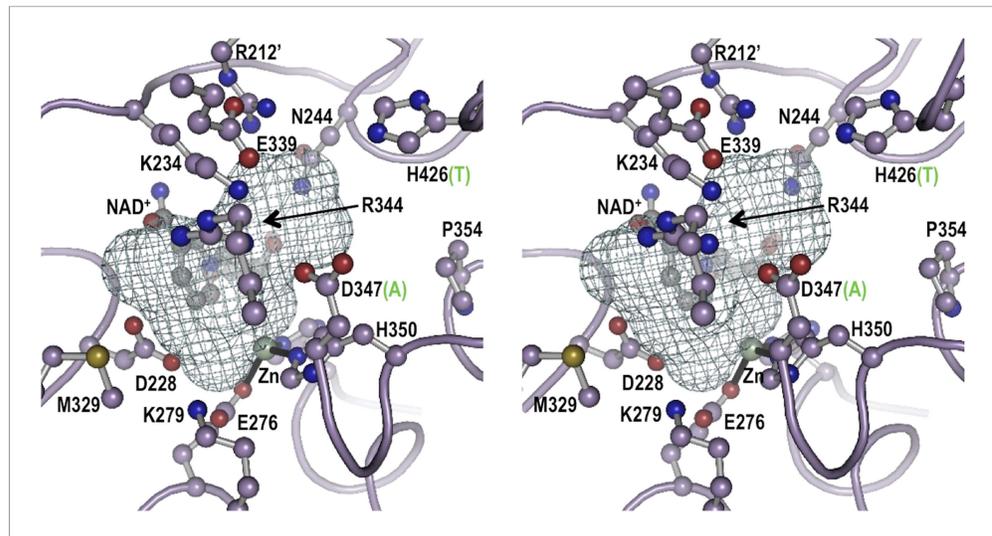

Figure 1—figure supplement 6. Stereoview for the modeled active site geometry of LOC100003999. Shown are the 13 active-site residues conserved in all EEVS enzymes (pale purple carbons), the NAD⁺ (gray carbons), and the Zn²⁺ atom (silver sphere with black coordination bonds), along with a mesh that delineates the pocket suitable for binding an SH7P substrate. Residue numbers in LOC100003999 identifying twelve of the active site residues are shown; the third metal ligand, H366, is behind the zinc and is not labeled. For the two positions that differ between EEVS and DDGS, the residue type present in DDGS is shown in green in parentheses. Figure made with Pymol (Schrödinger L. *The PyMOL Molecular Graphics System, Version 1.3.*) using the coordinates of ValA, an EEVS from *S. hygroscopicus* subsp. *jinggangensis* 5008 (Kean *et al.*, 2014). DOI: 10.7554/eLife.05919.010

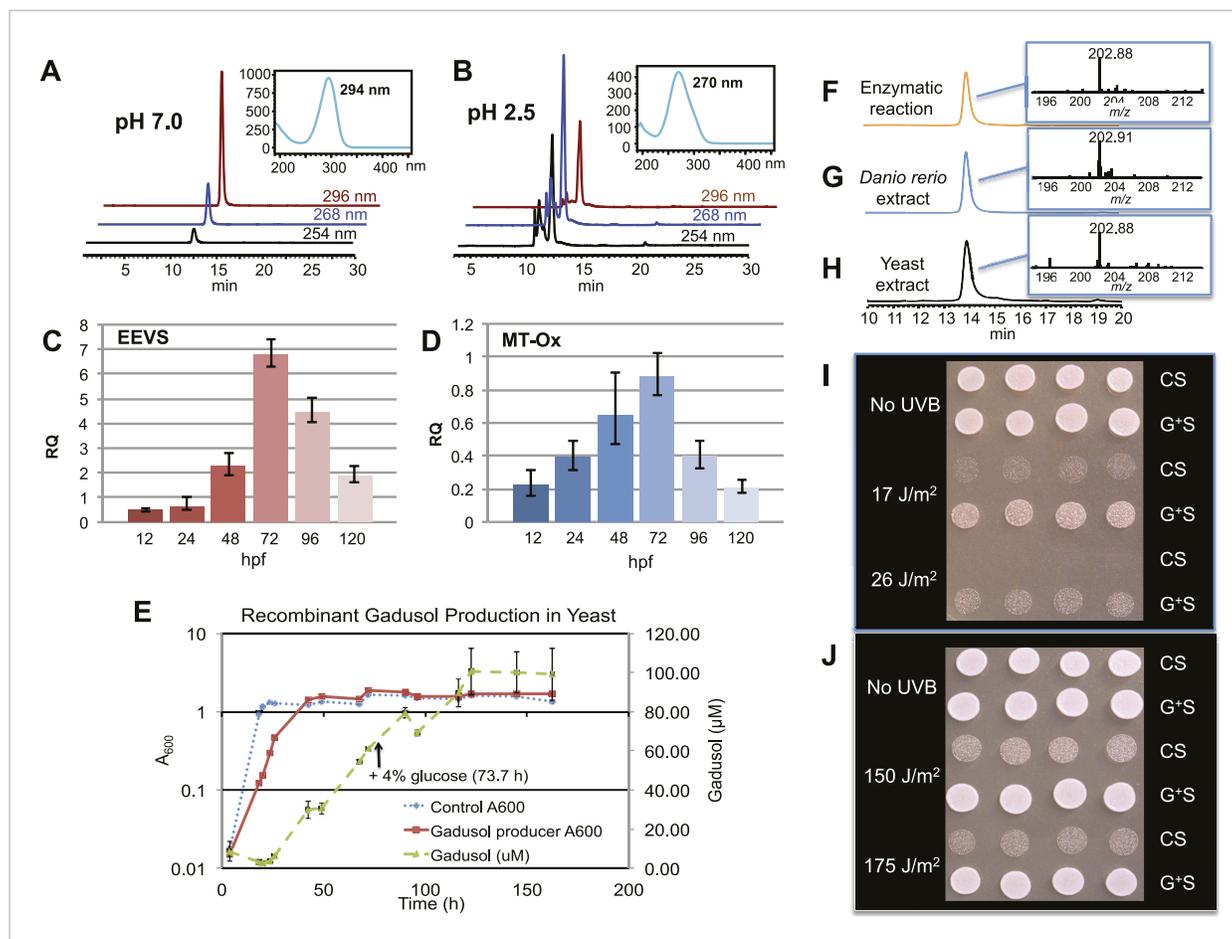

Figure 2. Production of gadusol in zebrafish and yeast and its sunscreen activity. **(A–B)** HPLC traces and UV absorptions of gadusol produced from *Escherichia coli* cell-free extract containing EEVS and purified MT-Ox protein at pH 7.0 and 2.5. **(C–D)** Transcription patterns of EEVS and MT-Ox genes during zebrafish embryonic development. qRT-PCR analysis of mRNA isolated from zebrafish embryos ($n = 3$) at 12, 24, 48, 72, 96, and 120 hpf. **(E)** Time course of gadusol production in yeast harboring the zebrafish genes. The yeast was cultured in YNB + 2% glucose supplemented with leucine and lysine at 30°C for 2 days, and growth was monitored as A_{600} values (control, dotted blue line; gadusol producer, solid red line). Gadusol concentration in the supernatant of 20 ml cultures ($n = 3$) was monitored as A_{296} values in 50 mM phosphate buffer, pH 7.0 (dashed green line) corrected for non-gadusol background absorbance in the control supernatant, normalized to A_{600} value. Gadusol was quantified based on an extinction coefficient of $21,800 \text{ M}^{-1} \text{ cm}^{-1}$ in 50 mM phosphate buffer, pH 7. **(F–H)** Comparative HPLC analysis of gadusol from recombinant enzymatic reaction, zebrafish extract, and yeast extract. **(I)** Gadusol suppresses the UVB sensitivity of a *rad1Δ* yeast mutant; and **(J)** Gadusol increases the UVB tolerance of a wild-type (*RAD1*) strain. Cells suspended in control supernatant (CS) or gadusol⁺ supernatant (G+S) were irradiated with UVB and subsequently spotted in 3 μl aliquots ($n = 4$) onto YEPD plates, which were incubated at 30°C for 24 hr.

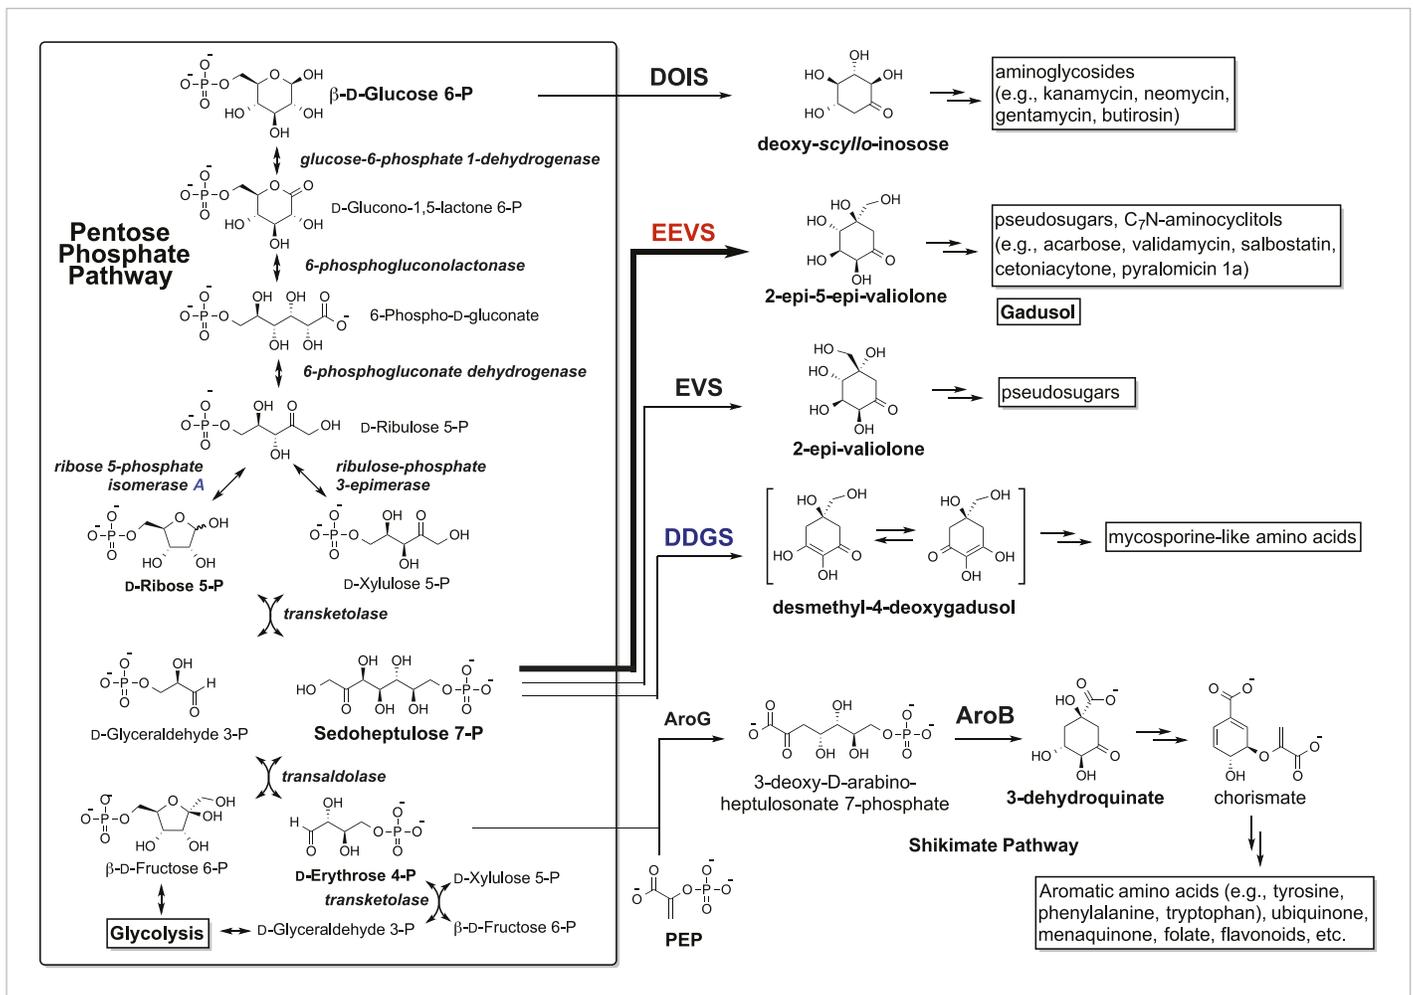

Figure 2—figure supplement 4. The Pentose Phosphate Pathway (Asamizu et al., 2012) and the shunt pathway to gadusol.

DOI: 10.7554/eLife.05919.016

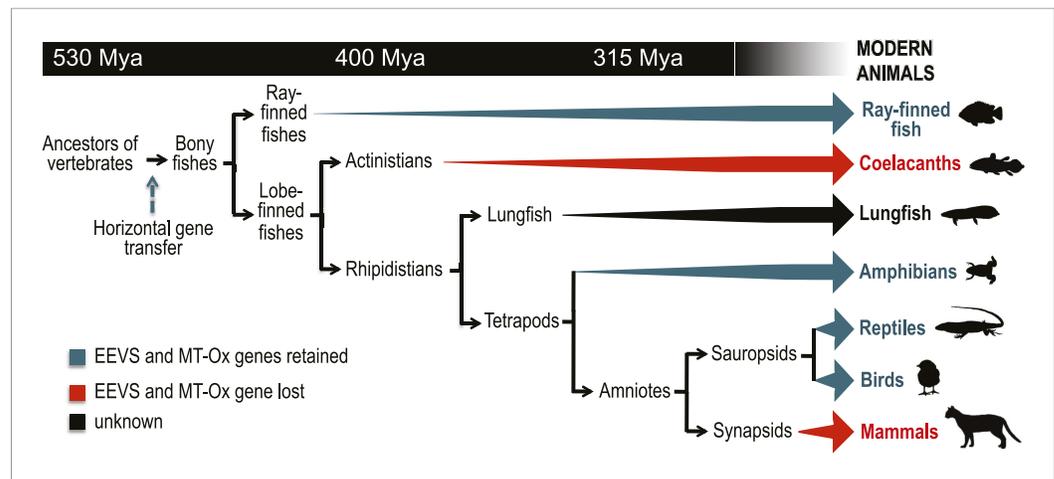

Figure 3. Model timeline for the evolution of the EEVS and MT-Ox genes in vertebrates. The genes entered an early vertebrate genome as a linked pair (vertical blue arrow) and were retained in the modern ray-finned fish, amphibians, reptiles, and birds as indicated by thick dark cyan arrows. Coelacanths and mammals lost the genes (thick red arrows). No full genome sequence is available for assessing the presence of EEVS and MT-Ox in lungfish. The phylogenetic trees of the EEVS and MT-Ox proteins or mRNA from a selected set of vertebrates can be found in **Figure 3—figure supplements 1–3** and **Supplementary files 1, 2**.
