

Twenty micrograms of total protein from cells transfected with 0.5 μ g of Emerin-GFP and different concentrations of the PROTAC-p97 using the Nb87 (anti- α -synuclein, used here as a negative control) were loaded. Specifically, cells were transfected with 2 or 4 μ g of **p97-PROTAC-Nb87**, or with **4 μ g of an Empty vector**. The experiments were performed in duplicate using independent samples

The same membrane was used; two films are shown corresponding to different exposure times.
